

## Module 5: Disk-based Index Structures

### Lecture 18: General Framework

[Prev topic](#)[Next topic](#)[Prev page](#)[Next page](#)

The Lecture Contains:

- General framework for hierarchical object-based index structures
- Exact match query or point query
- Range searching
- kNN searching
  - kNN searching order

## General framework for hierarchical object-based index structures

- Objects bounded by a hyper-dimensional **bounding rectangle** or **bounding box** or **bounding sphere** or **bounding convex polygon**
- Total of  $N$  objects
- $M$  objects of one level  $t$  into a bigger object of the next level
- Bigger object  $D_i$  at level  $i$  encompasses all smaller objects  $D_{i+1}$  at level  $i + 1$
- Total number of bounding objects is
 
$$\lceil N/M \rceil + \lceil N/M^2 \rceil + \dots = O(N/M)$$
- Total number of objects is, therefore, still  $O(N)$
- Hierarchy is called **object pyramid**
- Provides multi-resolution representation of database objects

Exact match query or point query

- Query point  $q$ 
  - Start with level 0
  - At level  $i$ , determine if  $q$  is in object  $D_i$ 
    - If no, return
    - If yes, recurse for all child objects in  $D_{i+1}$
- Example
  - $q$  is in  $T$ , so recurse
  - $q$  not in  $O$ ,  $R$ ,  $P$  but in  $S$
  - Proceed search to  $S$
- May follow multiple paths when objects are non-disjoint
- May end up doing more work than sequential scan

## Range searching

- Query point  $q$  and a distance radius  $r$
- Can be found by region intersection
  - Region C is unnecessarily searched
  - Extra space increases with dimensionality
- Compute minimum and maximum distances to regions
  - If minimum  $> r$  (C,D,I,L,K), no point in answer set-prune
  - If maximum  $\leq r$  (F), all points in answer set-report
  - Otherwise (A,B,E,G,H,J), not sure-recurse into the region

kNN searching

- Query point  $q$  and a positive integer  $k$
- Maintain heap of  $k$  current estimates and  $k^{\text{th}}$  distance  $d_k$
- Compute minimum and maximum distances to regions
  - If minimum  $> d_k$  , no point in answer set { prune
  - If maximum  $\leq d_k$  and region contains at most  $k$  points, all points in answer set- insert into heap
  - Otherwise, not sure-recurse into the region

## kNN searching order

- Efficiency depends on order in which regions are searched
  - Suppose  $k = 2$
  - Starting with F results in better pruning than with L
  - For root T,  $\langle S, O, R, P \rangle$  order is better than  $\langle P, R, O, S \rangle$  order
- Start with the region with lowest minimum
  - Sorting or comparison among regions
- Maintenance of heap
- More complex and time-consuming than range querying
  - Eorts to estimate range  $r$  for  $k$  neighbours
